### Abstract

For the purpose of finding solutions to optimize the classical involute profile, usually use for cylindrical gear, the present study aims as research direction, to modify that profile for improving the overall performance of gears. Gear optimizing will be made using advanced methods of calculation.

### 1. Introduction

Throughout the world, becoming more gears are manufactured by injection mold plastic, metal powder sintering or by cutting metal. Therefore, restrictions which are increasingly more, can be forgotten since the beginning of the project, when gears are made by traditional methods of cutting and grinding.

Therefore, use computer programs is heady necessary, because bring a clear support in process design, in the decrease time and cost of designing and implementing a project.

Thereby, opens up new possibilities for optimizing gears, endeavoring at a wide range of improvements: reducing noise, increasing of lift gear characteristics. With adequate support came from the calculation and optimization software for gears, this improvements will can be made without any problem. This opens new horizons for improving gears.

In the future will be enhanced following trends (visible even today):

- more metals will be replaced with plastic material
- significant reductions in noise and vibration of gears
- characteristics improvement (design of small gears but with the same or even higher performance than traditional gears)
- the use of specific forms of teeth

### 2. Addendum optimization

Safety factor against bending strength increases significantly if the connection radius of involute tooth addendum is substantially increased (modified). Even if gear cutting have carefully rounded edges, manufacture of gear using the generation methods by rolling, does not guarantee getting a good tooth fillet radius.

The safety function can be substantially improved by a change of profile, which will be conducted outside the involute. Using software to calculate and determine the stress, improvements can be checked directly.

It is clear that the geometry of the tooth, affecting the strength of the tooth and as a result we need an optimization of the addendum. As a condition it's require increasing tooth resistance. If tooth fillet it's made with non-standard curves, where it is desirable to study addendum stress, not be neglected graphical methods of analysis.

They will be examined three types of fillet:

- fillet with  $\rho^*_{fp} = 0,38$
- fillet with  $\rho^*_{fp} = 0,45$
- fillet optimization (elliptical)

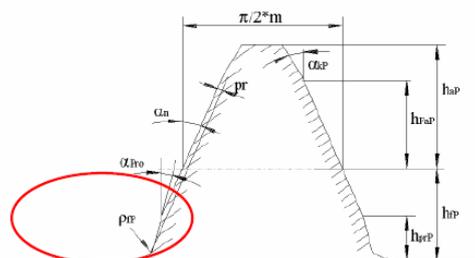

Fig. 1. Reference profile of gear [7]

According to ISO 6336, the critical cross section in the tooth root can be found via the 30° tangent of the root contour. YF and YS are then calculated as shown in formulas (1) and (2) respectively:

$$Y_F = \frac{6 \cdot h_{Fe} \cdot \cos \alpha_{Fen}}{m_n \left( \frac{S_{Fn}}{m_n} \right)^2 \cdot \cos \alpha_n} \quad (1)$$

$$Y_S = (1,2 + 0,13 \cdot L) \cdot q_S \left[ \frac{1}{1,21 + \frac{2,3}{L}} \right] \quad (2)$$

The resulting root stress is then calculated according to formula :

$$\sigma_F = \sigma_{FO} \cdot K_A \cdot K_V \cdot K_{F\beta} \cdot K_{F\alpha} \leq \sigma_{FP} \quad (3)$$

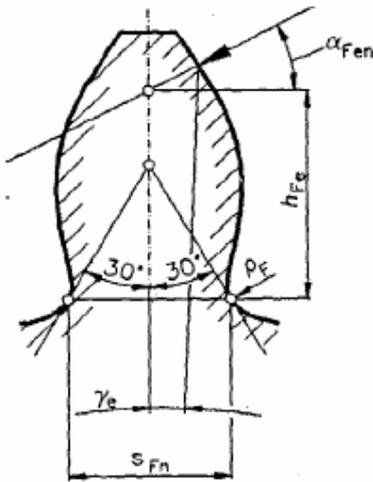

Fig. 2. Calculation of root stress according to ISO6336 [8]

If the tooth base geometry is change, the point defined above may not be the point where tension is highest.

### 3. Strength rating according to ISO6336

First determine of the safety factor will be in ISO 6336, method B. In this case, a standard reference profile (1.25 / 0.38 / 1.00) according ISO 53.2. Profil A is used.

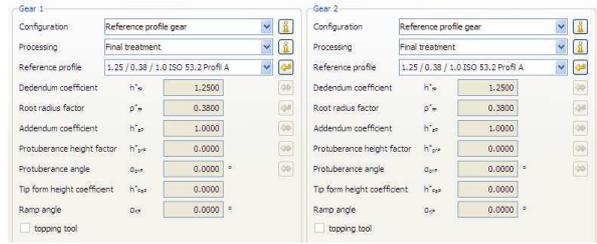

Fig. 3. Initial settings according to ISO 6336, method B

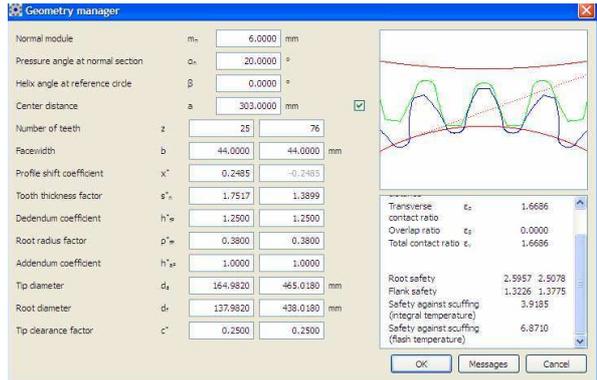

Fig. 4. The value of safety factor, geometric,  $\rho^*_{fp} = 0.38$

The next step is setting a different value of the radius of fillet,  $\rho^*_{fp} = 0.45$ . It will repeat all previous steps, resulting from the performance calculation following report:

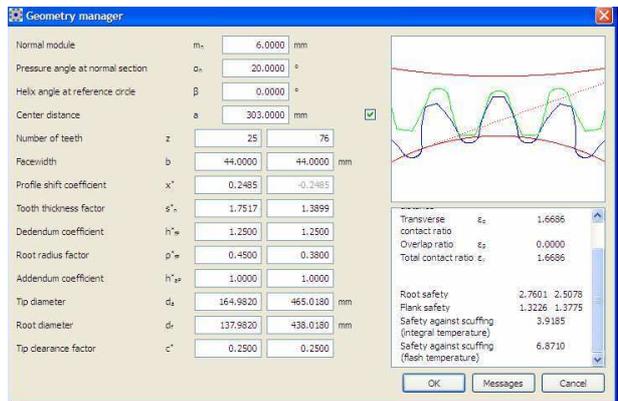

Fig.5. The value of safety factor, geometric,  $\rho^*_{fp} = 0.45$

It is noted that the value of safety factor increased with increasing radius of fillet

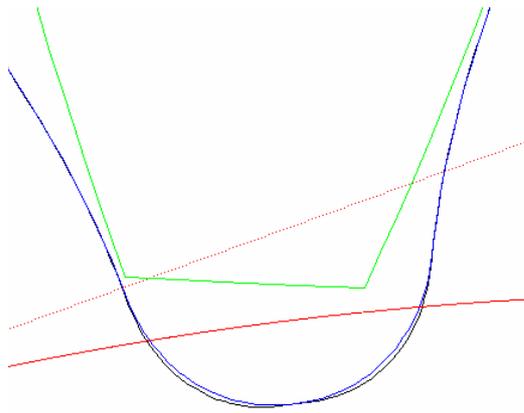

Fig. 6. Superimposed representation of the two profiles

#### 4. Strength rating using graphical method

The possibility to setting the gear is an undeniable advantage when trying to design an optimal gear. Enabling graphical method is performed as follows:

**System data**

Profile correction: none (only running-in)

Driving gear: Gear 1

Life factors  $Z_{N1}, Y_{N1}$  according to ISO6336: normal (reduction to 0.85 at  $10^{10}$  cycles)

Form factors  $Y_{Fa}, Y_{Fs}$ : using graphical method

Tooth contact stiffness: Following formulae of Standard (normal)

Small no. of pittings permissible

Load distribution coefficient:  $K_{v1}$  1.0000

**Pair data**

Transverse coefficient:  $K_{H\alpha}$  1.0000

Dynamic factor:  $K_{v}$  1.0259

Relative structure coefficient (scuffing):  $X_{H\alpha H\beta}$  1.0000

**Gear data**

	Gear 1	Gear 2
Number of load cycles	$N_L$ 528.9600	174.0000 $10^8$
Alternating bending factor	$Y_{Fa}$ 1.0000	1.0000
Grinding notch	$t_{q1}/\rho_2$ 0.0000	0.0000
Technology factor	$Y_T$ 1.0000	1.0000

Fig. 7. Enabling graphical method

Normal module:  $m_n$  6.0000 mm

Pressure angle at normal section:  $\alpha_n$  20.0000 °

Helix angle at reference circle:  $\beta$  0.0000 °

Center distance:  $a$  303.0000 mm

Number of teeth:  $z$  25 76

Facewidth:  $b$  44.0000 44.0000 mm

Profile shift coefficient:  $x^*$  0.2485 -0.2485

Tooth thickness factor:  $s^*_n$  1.7517 1.3899

Deendum coefficient:  $h^*_{f\alpha}$  1.2500 1.2500

Root radius factor:  $\rho^*_r$  0.3800 0.3800

Addendum coefficient:  $h^*_{fa}$  1.0000 1.0000

Tip diameter:  $d_a$  164.9820 465.0180 mm

Root diameter:  $d_f$  137.9820 438.0180 mm

Tip clearance factor:  $c^*$  0.2500 0.2500

Transverse contact ratio	$\epsilon_\alpha$	1.6686
Overlap ratio	$\epsilon_\beta$	0.0000
Total contact ratio	$\epsilon_\alpha$	1.6686
Root safety		2.4722 2.3592
Flank safety		1.3226 1.3775
Safety against scuffing (integral temperature)		3.9185
Safety against scuffing (flash temperature)		6.8710

Overlap ratio	$\epsilon_\beta$	0.0000
Total contact ratio	$\epsilon_\alpha$	1.6686
Root safety		2.8672 2.3592
Flank safety		1.3226 1.3775
Safety against scuffing (integral temperature)		3.9185
Safety against scuffing (flash temperature)		6.8710

Fig. 10 Optimized fillet

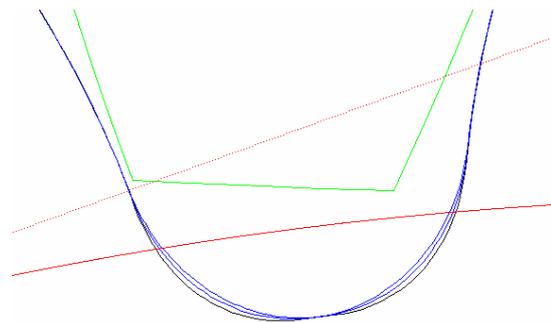

Fig. 11 Superimposed representation of the three profiles

Profile of basic rack that will process the toothed wheel which was amended in the addendum of tooth, there isn't one standard and therefore it's recommended designing such tools only for large production. These things have a financial justification, because the total costs of achieving those rack is reduced.

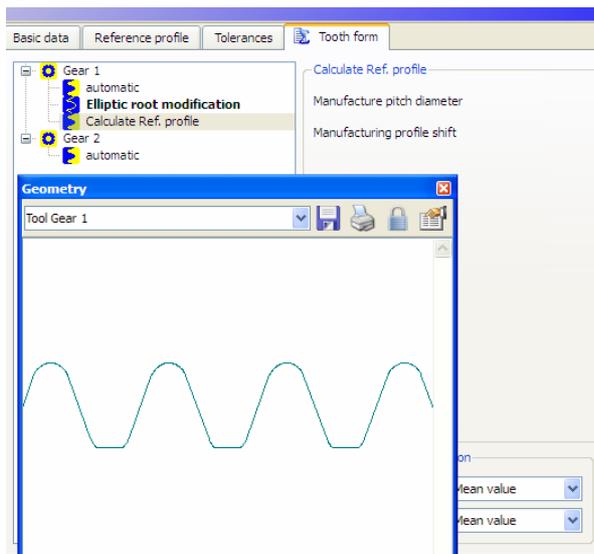

Fig. 12. Basic rack

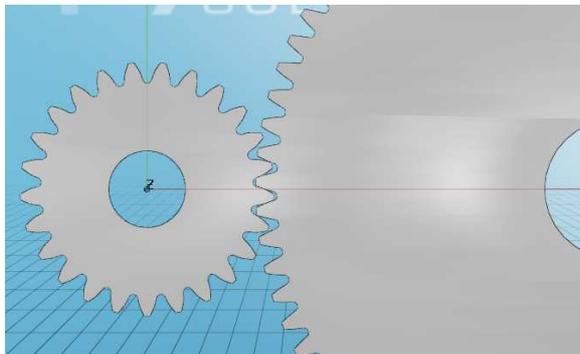

Fig. 13. Optimized gears

## 5. Conclusion

Tabel 1. Value of factor safety

	Safety factor according ISO 6336	Safety factor according ISO 6336, graphical method
$\rho^*_{TP} = 0,38$	2,5957	2,4722
$\rho^*_{TP} = 0,45$	2,7601	2,6477
Eliptical	2,7601*	2,8672

Improvement	6%	15%

It is clearly visible that by optimizing the geometry of the tooth, the factor of safety against breakage by bending can be increased by 15%. The only problem would be that, for processing the teeth, it takes a special tool (modified gear hob) so will only yield to large batch production.
